\textbf{ABSTRACT}

In this paper we implement a document retrieval system using the Lucene tool and we conduct some experiments in order to compare the efficiency of two different weighting schema: the well-known TF-IDF and the BM25. Then, we expand queries using a comparable corpus (wikipedia) and word embeddings. Obtained results show that the latter method (word embeddings) is a good way to achieve higher precision rates and retrieve more accurate documents.

\textbf{KEYWORDS}

Internet and Web Applications, Data and knowledge Representation, Document Retrieval.

1. INTRODUCTION

Document Retrieval (\textit{DR}) is the process by which a collection of data is represented, stored, and searched for the purpose of knowledge discovery as a response to a user request (query) \cite{1}. Note that with the advent of technology, it became possible to store huge amounts of data. So, the challenge has been always to find out useful document retrieval systems to be used on an everyday basis by a wide variety of users. Thus, \textit{DR} -as a subfield of computer science- has become an important research area. It is generally concerned by designing different indexing methods and searching techniques. Implementing an \textit{DR} system involves a two-stage process: First, data is represented in a summarized format. This is known as the indexing process. Once, all the data is indexed, users can query the system in order to retrieve relevant information. The first stage takes place off-line. The end user is not directly involved in. The second stage includes filtering, searching, matching and ranking operations.

Most of the proposed \textit{DR} systems are based on the cluster hypothesis \cite{2}. Highly ranked documents relative to a given user query form a cluster that is easy to identify in the case of one simple query. For many complex queries there are query-specific clusters that contain many relevant documents \cite{3} \cite{4}. If those documents are not presented as the top of the result list, this would decrease the retrieval performance. There have been many attempts to propose ranking query-specific clusters techniques \cite{5} \cite{6} \cite{7}. Most of proposed approaches simply compare
the representation of the cluster and the representation of the query. Some DR systems make use of additional features such as inter-cluster and cluster-document similarities [8][9][10]. Also, Query expansion [11] is another way to boost DR performance.

Query expansion (QE) [11] has been a research field since the early 1960. [12] used QE as a technique for literature indexing and searching. [13] incorporated user’s feedback to expand the query in order to improve the result of the retrieval process. [14][15] proposed a collection-based term co-occurrence query expansion technique, while [16][17] proposed a cluster-based one. Most of those techniques were tested on a small corpus with short queries and satisfactory result were obtained. Search engines were introduced in 1990s. Previously proposed techniques were tested on bigger corpora sizes. We noticed that there was a loss in precision [18][19]. Therefore, QE is still a hot search topic, especially in a context of big data.

To measure the accuracy of a DR system, there are generally two basic measures [20]: 1) Precision: the percentage of relevant retrieved documents and 2) Recall: the percentage of documents that are relevant to the query and were in fact retrieved. There is also a standard tool known as the TRECEVAL tool. It is commonly used by the TREC community for evaluating an ad hoc retrieval run, given the results file and a standard set of judged results.

In this paper we implement a document retrieval system using the Lucene toolkit [21]. Then we investigate the relevance of query expansion using parallel corpora and word embeddings to boost document retrieval precision. The next section describes the proposed system and gives details about the expansion process. The third one describes, and analyses obtained results. The last section concludes this paper and describes the future work.

2. METHODOLOGY

In this section, we present the structure of our Lucene system. First, we describe its core functions. In addition to that we describe some pre-processing operations as well as the evaluation process.

2.1. System Overview

Lucene is a powerful and scalable open source Java-based Search library. It can be easily integrated in any kind of application to add amazing search capabilities to it. It is generally used to index and search any kind of data whether it is structured or not. It provides the core operations for indexing and document searching.

Figure 1: Proposed document retrieval system architecture.
Generally, a Search engine performs all or a few of the following operations illustrated by the above Figure. Implementing it requires performing the following actions:

- **Acquire Raw Content:** it is the first step. It consists in collecting the target contents used later to be queried in order to retrieve accurate documents.
- **Building and analyzing the document:** It consists simply in converting raw data to a given format that can be easily understood and interpreted.
- **Indexing the document:** The goal here is to index documents. So, the retrieval process will be based on certain keys instead of the entire content of the document.

The above operations are performed in an off-line mode. Once all the documents are indexed, users can conduct queries and retrieve documents using the above described system. In this case, an object query is instantiated using a bag of words present in the searched text. Then, the index database is checked to get the relevant details. Returned references are shown to the user. Note that different weighting schemes can be used in order to index documents. The most used ones are tfidf (the reference of the vectoral model) and BM25 (the reference of the probabilistic model).

Typically, the tf-idf [22] weight is composed by two terms: the first one measures how frequently a term occurs in a document. It computes the normalized Term Frequency (TF) which is the ratio of the number of times a word appears in a document by the total number of words in that document. The second term known as the inverse document frequency (IDF) measures how important a term is. It computes the ratio of the logarithm of the number of the documents by the number of documents where the specific term appears.

Given a query $Q$, containing keywords $q_1$, ..., $q_n$ the BM25 score of a document $D$ is:

$$score(D, Q) = \frac{\sum_{i=1}^{n}(q_i \cdot f(q_i, D), (k_1 + 1))}{f(q_i, D) + k_1 \cdot (1 - b + b \cdot \frac{|	ext{avgdl}|}{D})}$$

where $f(q_i, D)$ is $q_i$’s term frequency in the document $D$, $D$ is the length of the document $D$ in words, and avgdl is the average document length in the text collection from which documents are drawn. $k_1$ and $b$ are free parameters, usually chosen, in absence of an advanced optimization, as $k_1 \in [1.2, 2.0]$ and $b = 0.75$. $IDF(q_i)$ is the IDF (inverse document frequency) weight of the query term $q_i$. It is usually computed as:

$$IDF(q_i) = \log \frac{N - n(q_i) + 0.5}{n(q_i) + 0.5}$$

where $N$ is the total number of documents in the collection, and $n(q_i)$ is the number of documents containing $q_i$.

### 2.2. Query Expansion using a Comparable Corpora and Word Embeddings

In order to improve system accuracy, we proposed two techniques of query expansion. The first one uses Wikipedia as comparable corpus. The second one uses word embeddings. The main purpose is to make the query more informative while preserving its integrity.
2.2.1. Query Expansion using a Comparable Corpus

First, we use Wikipedia as a comparable corpus to expand short queries. For this purpose, we tested two slightly different approaches.

- **Query expansion by summary**: We extracted key-words from the query using the Rake algorithm [25]; a domain-independent method for automatically extracting keywords. We ranked keywords based on their order of importance, we took the most important one. Then, we used it to query Wikipedia. We summarized the first returned page; AKA, we made a short summary of one sentence and we concatenated it to the original query.

- **Query expansion by content**: We extracted key-words from the query using the Rake algorithm. We ranked keywords based on their order of importance. Then, we took the most important one and we used it to query Wikipedia. Therefore, we concatenated titles of the top returned pages to the original query.

2.2.2. Query Expansion using Word Embeddings

Word embeddings are also used to expand the queries. We assume that the concept expressed by a given word can be strengthen by adding to the query the bag of words that usually co-occur with it. For this purpose, we used the Gensim implementation of word2vec using three different models: glove-twitter-25, glove-twitter-200, fasttext-wiki-news-subwords-300 and glove-wiki-gigaword-300 [26].

3. EXPERIMENTS, RESULTS AND DISCUSSION

3.1. The Data Set

For experiments, we used a subset of the Trec dataset. It is a news corpus. It consists in a collection of 248500 journal article covering many domains such as economics, politics, science and technology, etc. First, we performed pre-processing of our corpus by removing stop words, applying stemming or lemmatization. Stemming is the process of transforming to the root word by removing common endings. Most common widely used stemming algorithms are Porter, Lancaster and Snowball. The latter one has been used in this project. In lemmatization, context and part of speech are used to determine the inflected form of the word and applies different rules for each part of speech to get the root word (lemma). Obtained results using different pre-processing strategies are reported in the next section.

The most frequently and important basic measures for document retrieval effectiveness are precision and recall [27]. Precision is simply the probability given that an item is retrieved it will be relevant and recall is the probability given that an item is relevant it will be retrieved. In this work, we use the TRECEVAL program [28] to evaluate the proposed system. It uses the mentioned above NIST evaluation procedures.

3.2. Results and Discussion

During our experiments we used three measures of precision:

- **P5**: Precision after 5 docs retrieved.
- **P100**: Precision after 1000 docs retrieved.
- **MAP**: Mean Average Precision
Obtained results are reported in Table 1, Table 2, Table 3 and Table 4.

**Table 1:** The importance of pre-processing

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Metric</th>
<th>original data</th>
<th>stemmed data</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>P5</td>
<td>P10</td>
<td>Map</td>
</tr>
<tr>
<td>Short queries</td>
<td>0.192</td>
<td>0.026</td>
<td>0.115</td>
</tr>
<tr>
<td>Long queries</td>
<td>0.194</td>
<td>0.030</td>
<td>0.139</td>
</tr>
</tbody>
</table>

**Table 2:** TFIDF VS. BM25

<table>
<thead>
<tr>
<th>weighting schema</th>
<th>Metric</th>
<th>TFIDF</th>
<th>BM25</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>P5</td>
<td>P10</td>
<td>Map</td>
</tr>
<tr>
<td>Short queries</td>
<td>0.196</td>
<td>0.172</td>
<td>0.148</td>
</tr>
<tr>
<td>Long queries</td>
<td>0.236</td>
<td>0.266</td>
<td>0.148</td>
</tr>
</tbody>
</table>

Table 1 shows the system accuracy when using non-processed Vs. pre-processed data. It proves that pre-processing helps to achieve better precision rates. While, Table 2 shows results when using different weighting schema: better results are obtained by using the BM25 weighting schema. Notice here that we performed the same pre-processing before conducting experiences using different weighting schema.

**Table 3:** Obtained results when expanding queries by summary and content

<table>
<thead>
<tr>
<th>Expansion Strategy</th>
<th>Metric</th>
<th>O</th>
<th>T</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>P5</td>
<td>P10</td>
<td>Map</td>
<td>P5</td>
</tr>
<tr>
<td>Short queries</td>
<td>0.196</td>
<td>0.172</td>
<td>0.148</td>
<td>0.195</td>
</tr>
</tbody>
</table>

Table 3 displays obtained results when applying query expansion using a comparable corpus. We conducted three experiences: T (using expanded queries by title), S (expanded queries by topic) and we compared their results to those obtained by our original set of short queries. Notice here that we performed the same pre-processing and we used the same weighting schema. Obtained results show that expanding queries through titles of the top returned Wikipedia pages gives approximately the same precision rates with the original procedure. Whereas, expanding queries through the summary of the Wikipedia top page messes up the system accuracy.

**Table 4:** Obtained results when expanding queries through word embeddings

<table>
<thead>
<tr>
<th>Model</th>
<th>O</th>
<th>WE1</th>
<th>WE2</th>
<th>WE3</th>
<th>WE4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metric</td>
<td>P5</td>
<td>P1000</td>
<td>Map</td>
<td>P5</td>
<td>P1000</td>
</tr>
<tr>
<td>Short queries</td>
<td>0.196</td>
<td>0.030</td>
<td>0.148</td>
<td>0.164</td>
<td>0.026</td>
</tr>
</tbody>
</table>

Table 4 shows results when expanding queries using word embeddings. We used the Gensim implementation of word2vec. We tested three different models: glove-twitter-25 (WE1), glove-twitter-200 (WE2), fasttext-wiki-news-subwords-300 (WE3) and glove-wiki-gigaword-300 (WE4). Obtained results show that the system accuracy can be enhanced when taking in consideration the top 5 returned results. To achieve this goal, we should use the appropriate model: WE3, which is trained with a news corpus or WE4 which is trained using a very huge amount of data.
4. **CONCLUSIONS AND FUTURE WORK**

In this work, a DR system based on the Lucene toolkit is presented. Different weighting schema are tested. Results show that the probabilistic model (BM25) performs the vectoral one (TFIDF). Also, lead experiments show that query expansion using word embeddings improves the overall system precision. Meanwhile, using a comparable corpus doesn't necessarily lead to the same result. This paper can be improved by:

- Testing an interactive query expansion technique: experimental results show that the query expansion using a comparable corpus does not lead to higher precision rates. The precision rate depends on the efficiency of the Rake key word extractor algorithm. The main idea is to let users validate the automatically extracted keywords used later during the query expansion process.

- Testing a hybrid technique of query expansion: word embeddings can be applied on the result of the interactive query expansion phase. This may boost the system performance since the interactive query expansion will guarantee the use of significant words of the query. Also, using word embeddings will ensure retrieving relevant documents which do not necessarily contain words used in the query.
