INTEGRATED SPECIFICATION OF QUALITY REQUIREMENTS IN SOFTWARE PRODUCT LINE ARTIFACTS

Mworia Daniel, Nderu Lawrence and Kimwele Michael

Department of computing, Jommo Kenyatta University of Agriculture and Technology, Kenya

ABSTRACT

There are many calls from software engineering scholars to incorporate non-functional requirements as first-class citizens in the software development process. In Software Product Line Engineering emphasis is on explicit definition of functional requirements using feature models while non-functional requirements are considered implicit. In this paper we present an integrated requirements specification template for common quality attributes alongside functional requirements at software product line variation points. This approach implemented at analytical description phase increases the visibility of quality requirements obliging developers to consider them in subsequent phases. The approach achieves weaving of quality requirements into associated functional requirements through higher level feature abstraction method. This work therefore promotes achievement of system quality by elevating non-functional requirement specification. The approach is illustrated with an exemplar mobile phone family data storage requirements case study.

KEYWORDS

Software Product Line Engineering, Functional and Non-functional requirements, Quality attributes, feature variability, integration and requirements specification.

1. INTRODUCTION

In the history of requirements engineering, non-functional requirements (NFRs) were not considered alongside functional requirements until recently. NFRs problems are grouped into definition problems, classification problems, and representation problems. Representation of NFRs is a big challenge owing to their fuzzy nature where depending on how we define an NFR; its representation on a software specification document can make it appear like a functional requirement creating even more confusion in requirements documentation.

Despite the fact that there are many on-going efforts to determine in which stage of software development to integrate NFRs, researchers agree that taking NFRs into consideration during the early phases of any software engineering processes can improve the quality and agility of software[1].

There are various ways in which NFRs can be represented depending on the reason of their use and phase of the software development project. Goal-oriented approaches have advanced well-defined approaches to model NFRs at early stage of the requirement engineering process while at the architectural phase NFRs associated with particular components can be used to justify alternative designs [2].
Another very well-defined approach for representing NFRs is textual representation which involves documenting requirements in software requirement specification (SRS) through the use of templates. The most widely used textual requirements representation methods are the natural language-based templates [3].

In any software development process non-functional requirements (NFRs) analysis will yield performance requirements, business constraints, and non-functional properties or quality attributes (QAs). This work will focus on quality attributes requirements representation in software product line engineering (SPLE) where variability is critical and the operationalization of quality goals is closely interlaced with functional requirements.

In Software product line Engineering (SPLE) requirements engineering activities are carried out in the early stages of domain analysis & engineering (DA&E). A product-line is a set of products that share a common set of requirements, but also exhibit significant variability in requirements. In the requirements analysis stage, the requirements gathered in the previous stages are analysed and further refined. The commonalities and variabilities can be identified either by using product line specific techniques or other techniques such as feature-oriented domain analysis (FODA) and family-oriented abstraction, specification, and translation (FAST) [4].

SPLE exploits the similarities of the systems that belong to a product line and systematically handles the differences between them. Product line variability defines how product line applications may differ in terms of features, functional and quality requirements they fulfil. Like commonalities, product line variability is pre-planned by defining whether a given feature, functional or quality requirement is product line variability or not based on explicit decisions from all product management stakeholders [5]. Quality attribute variability can be due to functional variability causing indirect variation in qualities, and vice versa.

Most SPLE approaches typically cover the domain and application engineering processes, but set aside one activity important to companies which is analysis of non-functional properties (NFPs) or quality attributes and the evolution of SPL’s artifacts. The large part of most SPL methodologies is management of functional variability and the minor part of implementing quality variability is with annotations that are sometimes abandoned after a short period of time because of the lack of integration during the SPL development activities.

Literature review clearly demonstrates the aspect of variability in quality attributes has been “neglected or ignored by most of the researchers and attention mainly put in the functionality variability of the products. As observed in [3], most approaches to quality attributes incorporation in software product line development introduce the variability at the design level (e.g., within sequences diagrams) instead of modeling the variability of the Quality attributes earlier on in the development process, such as the requirement level or at the architectural level. Our approach addresses this gap by considering and integrating quality attributes at the domain requirements analysis and specification phase.

Feature Models are the most widely used variability language, that model variability by means of high level features that are close to requirements specification. During feature model analysis it is important to consider quality attributes as part of the model variability alongside functional features to generate more than one solution, the variation points be made explicit and document the decision models with the knowledge necessary to ponder about the better solution for each product to be derived. This work therefore proposes an approach that will support identification and integration of quality attributes with the functional features at respective variation point levels during domain requirements analysis phase based on higher-level abstraction of common features among variants.
The contribution of this paper is to provide support, applying domain analysis and variability management techniques, to the identification and representation of quality requirements in SPL development. This paper focus on analysis and specification of quality requirements alongside the functional requirements in the early stages of SPL development taking as input the domain requirement documents together with feature diagrams. The approach proposes the use of a textual integrated requirements template to extract common functional and quality attribute requirements at the SPL variation point. Further the Proposed approach extends the feature based analysis of domain requirements by focusing on the product family variation points to generate common functional quality attributes among the product family variants which are then stored as aspectual components to promote reuse.

The remainder of this paper is organized as follows. Section 2 reviews related work. Section 3 describes the proposed approach while Section 4 applies the conceptual approach on a case study. Finally, Section 5 summarizes the contributions of this work and outlines directions for further research.

2. RELATED WORK

A range of research works have been carried out that seeks to support incorporation of NFRs in software product line Engineering (SPLE) process. Whereas there is no agreed upon stage of integrating NFRs in to the software development process efforts in literature focus more on the solution space ( design , architectural choice, evaluation and testing) than the problem space( requirements elicitation and analysis) [6].Some of the relevant approaches addressing this issue are presented below.

2.1. Quality attributes Integration based on Extension of UML models

In an effort to capture variability of quality attributes using Model-Driven Development (MDD), [7] recommend annotating the base model by means of extensions to the base modeling language. They add generic annotations related to a quality attributes like performance to the UML model which represents the set of core reusable domain assets. The concrete UML annotations are based on UML profiles with stereotypes to achieve desired quality attributes modeling. However annotations of the application base model prevents its reuse as well as that of derived quality attributes.

FeatuRSEB is a popular approach which combines FODA and the Reuse-Driven Software Engineering Business (RSEB) method . In FeatuRSEB UML-like notational constructs are used for creating Feature Diagrams, with explicit representation of variation points, and variants and explicit graphical representation for feature constraints and dependencies. Non-functional requirements are captured as feature constraints. Product Line Use Case modeling for System and Software engineering (PLUSS) is an approach that borrows from FeatuRSEB to combine Feature Diagrams and Use Cases. This approach makes explicit decomposition of the operator to compose a feature by introducing two new types of nodes; single adapters (represent XORdecomposition) and multiple adapters (OR decomposition).This approach however does not explicitly handle quality attributes.

2.2. Architectural based Quality Attributes integration Approaches

Extension of the feature model mechanisms from ATAM (Architecture Trade-off Analysis Method) can be used to represent quality attributes, their variability with respect to optionality and levels, their influence on quality of the functional, architectural and implementation features (indirect variation). The extended feature model presents both functional and quality concerns as
the fundamental element used to capture the variability in subsequent phases of design and implementation.

At the architectural phase existing works address quality attributes variability jointly with the variability of base applications. [16] propose the RiPLE-DE (RiSE Product Line Engineering - Design Engineering) process approach presenting the variability of quality attributes in feature diagrams and in order to derive the desired quality attributes the diagrams are enhanced with information of the base application (e.g., the system's response measure). The variation of attributes is presented in form of numerical values that will be used in evaluation of the resulting architecture designing SPL architectures that involve systematic transformation of functional requirements and quality.

Quality-driven Architecture Design and quality Analysis (QADA) is a method for incorporating attributes into software architectures, which do not however explicitly consider quality. Another approach in [8] suggest the influence of each feature on a non-functional property be predicted before generating the configurations. Their approach however focuses on predicting the effects of the features on individual applications instead of focusing on recurrent quality attributes at the domain engineering phase to promote reuse.

2.3. Goal Oriented NFR integration Approaches

[9] conclude that there is an association between software product lines and goal analysis and thus one can use goal-driven requirements approaches for feature specification. Goal analysis modeling can support auto-generation of feature models in SPL. In SPL paradigm, an integrated modeling framework (F-SIG, Feature-Softgoal Interdependency Graph) extends the feature modeling with concepts of goal-oriented analysis. This goal oriented analysis is aimed at letting developers to capture design rationale of inter-dependencies between variant features and quality attributes during the design of product line architecture, and evaluate the impact of variant features selected for a target system.

The goal driven and Chung’s NFR framework approach has been widely used by researchers to integrate NFRs into the software development process. Whereas functional requirements are considered as hard goals, non-functional requirements are presented as soft goals in the analysis specification process. The correlation is shown as a directed graph where the nodes are hard goals, the target nodes are soft goals and the edges are represented by the + or – characters. However software developers pay more attention to functional needs of a software and NFRs such as performance, usability, reliability and security are usually handled later in an ad-hoc manner mainly during the system testing phase [10].

NFRs can be essential in all aspects of Software Product Line (SPL) like in situations where a requirement may cuts across all product lines and the variation exists in the contextual application. [10] recommended extending the Product Line Use Case modeling for System and Software engineering (PLUSS) to include other NFRs other than the performance NFRs only by use of discrete values to express degree of satisfice-ability and for security NFR represent the levels of data protection as outlined in the NIST standard. This approach however focuses on how single NFRs can be evaluated for satisfiability during product testing.

[11] also proposes an approach of modeling quality attributes with the variability of the base application based on domain experts’ judgments using the Analytic Hierarchical Process (AHP). This captured quality knowledge of domain experts is used for quality aware product. Any functionality that affects quality attributes is referred to as a contributor but do not explicitly deal with the quality attributes.
[12] advanced another interesting approach known as Concern-Oriented Reuse (CORE), a general-purpose software development which leverages on the strength of Model-Driven Engineering (MDE), Component-Based Software Engineering (CBSE), SPL, feature oriented and aspect-oriented software development, and goal modeling to promote reuse. This approach entails encapsulating all software functional and non-functional Requirements in reusable units called concerns. As much as they do not explicitly deal with quality attributes, the encapsulation of concerns is what our proposed approach recommends. The other difference with our work is the fact that they model variability of the component interfaces and not integration of functional and quality attribute concerns like our proposal suggest.

2.4. Domain Requirements Analysis and Specification

Our paper focuses on the textual representation of quality attributes alongside functional requirements in software product line so as to support documentation and subsequent phases of development. We therefore mention related works in the line of textual analysis and representation of quality attributes alongside FRs both in SPLE and single-system development approaches.

According to [13] the most common approaches for analysis and specification for software product lines can be categorized as product based specification, where the features of each individual product are specified one by one and feature based specification, where individual features are specified without links to any other features. There is also the family based specification approach where specification can be written for all the features of the product line with variable parts for individual features. Our approach to SPLE specification is similar to the family based specification with variable parts for individual features presented in a text based specification method.

Whereas [14] note that software product lines do not have a de facto standard for requirements analysis and specification there have been several attempts that promote to connect goal-oriented approaches with this task. [9] observe that feature modeling is the core of software product line engineering and a de facto standard in modeling variability in SPL.

Extended feature models can address representation of domain Quality attributes (such as performance, availability, security or safety) including their variation dimensions. This work extends this approach by considering the quality attributes variability alongside the functional variability at variation points. Existing requirements documentation methods separate functional and quality attribute requirements whereas at the variation point there could be common variation to all possible family members that could be integrated and documented together as aspectual components for easier reuse.

Volere Requirements Specification Template is a well-established method for recording requirements in a structured way. The method supports the recording of user goals and requirements in the template according to their rationale, associated stakeholder, priority and contextual details. There are different templates for specific NFRs like usability, maintainability security among others in the Volere documentation.
The Volere Requirements Specification Template documentation inspired several other works including [15] and [16]. A problem with the usage of such templates is that they are useful only when a single person is responsible for managing them. However, in a project where many people are working simultaneously, this can lead to inconsistent, contradicting and omitted requirements, and a need for a complex requirements management tool.

Apart from detailed tabular templates and models, several research works provide boilerplates (reusable sentences); a term referring to limited vocabulary sentences having specific placeholders to be completed in order to obtain semi-formal requirement sentences. [17] have presented an elicitation methodology by the use of their Non-functional Requirements Templates (NoRTs), which focuses on using generic statements (having core and optional parts) that become defined NFRs after adding required information. EARS approach provides a simple boilerplate for requirement templates that can be used for non-functional requirements as well.

18] use natural language processing techniques for identification of NFRs from requirements documents. The approach uses a language model and popular keywords for identification of NFRs. This work suffers from the limitation of the lexicon or keywords as most NFRs are domain dependent.

There have been different proposals for templates to support textual use case descriptions of Software Product Lines where fine-grained variation could be specified at the end of the SPL use cases with a template consisting of the following elements; name, type, line of the use case (the target of the variation), and description.

Another textual use case template found in [19] aimed at specifying the variation points through OPT and ALT tags where any text fragment of the textual use case description may be variant is explicitly marked by pairs of the XML-like tags <variant> and </variant>. [20] proposed a simpler tag notation where the tags are used only for marking variation points in use case scenarios of SPL. Each tag is expanded in a section called “Variations” and is mapped to the Orthogonal Variability Model (OVM).

[5] further observe organizations can also use their own specification templates or some standardized Software Requirements Specification (SRS) document structures to specify product line requirements. In order to capture the integrated quality attribute requirements at variation
points we propose to use own specification templates for documenting each variation point based on structured document templates such as extensible markup language (XML) which allow hierarchical representation of common and variable requirements.

It is clear from the literature review that existing SPL modeling frameworks mainly focus on feature models, use cases and domain specific requirements specification languages. These approaches represent functional and non-functional requirements in separate documents and diagrams, but our proposed approach recommends integrated specification document based on structured document templates such as extensible markup language (XML). The aspectual component development of the extracted functional quality requirement concern and the XML documentation can be handled using existing techniques in SPL research. The research works included in this section can be summarized as follows:

a) Existing models to integrating quality attributes into SPL development process do it more in the solution space (design, architectural choice, evaluation and testing) than the problem space (requirements elicitation and analysis).

b) All SPL approaches discussed in related work above support analysis of quality attributes in respect to evaluation of achievement degree of non-functional property (NFP) in the final product but do not address the variation analysis of the quality attributes at the product family variation points.

c) Most of the text-based tabular templates represent quality attributes as independent elements of requirements process. The need for NFRs’ relationship with specific functional requirements is not fulfilled by most of these efforts.

d) This work therefore focuses on textual extraction and integrated representation of functional quality attributes at respective variation points during domain requirements analysis phase based on higher-level abstraction of common features among variants. The functional quality attributes can then be included in requirements documents to achieve traceability and incorporation throughout the development process.

3. PROPOSED APPROACH

With ever increasing number of software development companies adopting Software Product Line (SPL) methodology as opposed to single-systems software development the field is also continuously changing. In terms of the process many approaches typically cover the domain engineering activities of variability modeling but ignore issues that matter to organizations such as the analysis of non-functional properties (NFPs) or quality attributes and the evolution of SPL’s artifacts[7]). A few organizations that attempt to implement NFP variability do so with annotations that are sometimes abandoned after a short period of time because of the lack of integration among the SPL activities.

A persistent challenge in SPL development has been the modeling and management of variations in their product lines. In SPL development variability exists at different levels of abstraction, including requirements variability (mainly feature based), architecture variability (mainly component based), and implementation variability (mainly code based). In most modern software systems variability can also be classified as variability in functional behaviour, variability in non-functional system properties and fault based variability. This work focuses on requirements variability and possible integrated specification of functional and quality requirements in the early phases of software product lines development.

From domain knowledge & stakeholders requirements documents, in the feature oriented analysis phase we can extract common functional quality attributes among the variants and use higher level feature abstraction method to map them to respective variation points as common
base concerns of an SPL. The Steps in the integrated specification of requirements at the SPL variation points are as follows.

3.1. Identification of variability point of interest from an SPL feature model

An established way of capturing commonalities and variability’s of a product-line system during early development stages is by use of Feature-Oriented Domain Analysis (FODA). In FODA a feature model presents requirements in a tree based feature diagram where functional features are decomposed into more fine-grained features that are either mandatory, optional, or alternative and optional features specify variability.

Since variability analysis determines where variability is needed in the product line and features represent system property or functions relevant to some stakeholder, a product family variation point could also yield members which also present common and variable requirements limited by the domain scope. This work therefore pursues the possibility of creating a requirement specification template that can support the integration of common functional and quality attributes in a software product line variation point. The integrated requirements can be stored as an aspectual component for reuse.

Product family variability is where a feature can have alternative implementations or variant implementations, which can be chosen to create different products. A variation point is each point in the software where different variant implementations from a variant population can be chosen from. Characteristics of a product that can be changed to produce a different product are called variation points. In terms of realization technique, a variation point can be the point where a class is chosen to be used or where code fragments are chosen to be run. Once you identify the related variant features of the product family in the graph a variation point can be marked with every set of related features [21].

3.2. Analysis of requirements at the variation point

One way to incorporate the non-functional requirements early in development of SPLs is to consider them at the variation point where common and variable features among the different variants can be analyzed to identify common functional and non-functional properties. The requirement commonality and variability applies to both functional and non-functional aspects with respect to family members. However there exists common quality factors that are associated with functional requirement in each domain such as security for banking systems, reliability for embedded systems and usability in general for most of the applications. Early identification of such requirements can facilitate development of reuse of aspectual components to serve all members of a product line family.

At each variation point the core and possible functional and non-functional requirements of the family members can be identified and analysed according to a structured specification template. Whereas non-functional requirements can be classified as Performance, quality and constraints requirements, our focus is quality properties that would assure end user satisfaction. NFRs and especially quality attributes have a close relationship with functional requirements especially in their operationalization. We therefore propose creating a relationship of certain quality factors with FRs as fulfilling the quality factors at the variation points level eventually supporting the NFRs satisfaction at the global level.

A major objective of Software product line engineering is maximizing the commonalities (platform or architecture) whilst minimizing the cost of variations (i.e., of individual products) to facilitating reuse in a predictive manner. Whereas several methods and tools were developed for
variability identification exist such as FODA, that are specifically focused on requirements, including Feature-oriented domain analysis (FODA), Natural Language (NL) requirements documents can also act as a source of variability information that can be used to define variability models [22].

Since a high level requirements can hide a family of different products this work pursues variability extraction based on analysis of high level requirement documents or features which when further decomposed can yield common quality attribute operationalization among the variants. These integrated requirements are functional quality attributes.

3.3. Integrated specification of functional and quality requirements to produce an aspectual component for the SPL

Existing SPL specification models mainly focus on feature models, use cases and domain specific requirements specification languages. These approaches represent functional and non-functional requirements in separate documents and diagrams. Whereas functional decomposition is done in feature diagrams and use cases the associated non-functional requirements are not explicitly defined. This work proposes a semi-formal approach using structured non-mathematical notations to organize information about functional quality requirements.

As [3] observed there are situations where a non-functional requirement affects neither a single functional requirement nor the system as a whole but a specific set of functional requirements. Such a case requires unique variability specification templates that ensure explicit documentation and adequate explicit traceability. The specification template can then be developed using the aspect oriented design methodology for reuse among the family members.

At the Variation point of a feature model we identify a dominant functional concern and decompose the system model hierarchically into sub-features that contribute to its realization. We also identify a core non-functional property (Quality attribute) of the domain at the variation point and refine it into specific quality concerns for each possible family member.

As argued in [23] even a cross cutting non-functional requirement within a software family such as security may differ in intensity levels such as intense security or moderate level of security. Non-functional requirements can be grouped into performance requirements, constraints and quality attributes. Whereas Constraints such as cost, efficiency or portability can be mapped to architectural or implementation decisions, quality attributes such as security, usability and error handling can be mapped directly to functional components and thus referred to as functional quality attributes (FQAs). These FQAs are normally required by several applications in a product line and therefore specialized components can assure their satisfaction.

An integrated textual requirements analysis template as in Table 1 can generate possible functional and non-functional requirements at the variation point exposing common functional quality attributes which apply to all members of the software product family with a common base at that variation point. The common functional-quality attribute set of requirements can then be stored as an aspectual component at the variation point of the primary feature model through a join relationship and the same can be applied at every level of variation point that presents similar characteristics.
Table 1. Elements of proposed variation point integrated requirements template.

<table>
<thead>
<tr>
<th>Variation point(Vp) Id</th>
<th>(description)</th>

<td>(description)</td>
</tr>
<tr>
<td>VpQualityConcern</td>
<td>(description)</td>
</tr>
<tr>
<td>VpFunctional-QualityConcern</td>
<td>(description)</td>
</tr>
</tbody>
</table>

The integrated functional-quality requirement becomes the final requirement description that will be used in all subsequent phases of software development including design decisions. This inclusion of quality attributes in functional description will remind the developers to consider them in all decisions and subsequent phases of software development [24].

Figure 2. Proposed approach for integrating quality concerns at SPL variation point.
4. **Case Study**

For practical demonstration of the proposed approach we present case study that consists of a simplified version of variability requirements from a mobile phone software product line family. Customizable software is necessary for a broad spectrum of domains (e.g., operating systems for diverse hardware) and hence our choice of mobile phone family data storage features programming.

Modern mobile phones are multifunctional and provide the ability to perform a wide range of actions beyond the common voice communication role. Common mobile phone features and utility functions include log in, call management, text messaging, storage, camera ringtones clock, and varying multimedia features. Among increasingly critical functions of a mobile phone is data storage which cannot only be extended with flash memory card device but also with online backup. Phones as storage devices hold personal, organizational and even proprietary data.

Research findings consistently show that a significant portion of mobile phone users are concerned about security of their mobile device, its data, or its application against a “casual” and unprofessional attack by children, spouses, friends, co-workers etc. Implementing this security feature for different members of the mobile phone family requires variability management in terms of functionality and quality attributes of the system. We will focus on variability of the phone data protection and user privacy enforcement mechanisms as requirements that expose functional quality attributes at the variation points.

i) Identifying variation point dimensions

![Figure 3: Mobile phone utility functions feature diagram](image)

ii) Requirements analysis and specification at variation point

From Figure 3 we focus on storage feature as a critical function in mobile phones today since they are being used as personal digital assistants (PDAs) for private and even corporate work. Variants in the mobile phone family line will present different abilities to satisfy that storage function. Assuming the following set of general user expectations from the phone family line expectations related to data storage:
Rq1. The phone shall have capacity to store data
Rq2. The phone shall have ability to extend storage capacity
Rq3. The phone shall have capacity to clear storage once full
Rq4. The phone may (optionally) permit transfer data to other devices
Rq5. The phone shall have capacity to read different file formats
Rq6. The phone shall ensure security of data
Rq7. The phone shall ensure user privacy

Rq6 and Rq7 are non-functional requirements and specifically quality requirements which must be achieved by all variants to some level of satisfaction through different mechanisms. Addressing the satisfaction of the two quality requirements involve consideration of functional quality attributes at respective family tree variation points.

At the level of domain analysis the requirements above will subject our feature graph to further functional decomposition to identify different phone capabilities to operationalize them with different mechanisms and limitations. The broad techniques of achieving the requirements is at the phone login, desktop, database and external interface points as shown in Figure 4 with further variability among the possible solutions.

![Figure 4. Mobile phone data security requirements feature diagram](image)

### iii) Integrated specification of Functional quality attribute requirements

Assuming we have three variants of the phone family that differ in their ability to satisfy the requirements Table 2 illustrates the possible scenarios:

<table>
<thead>
<tr>
<th>Variant Type</th>
<th>Ability to Satisfy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Smart</td>
<td>Rq1, Rq2, Rq3, Rq4, Rq5</td>
</tr>
<tr>
<td>Evolving</td>
<td>Rq1, Rq2, Rq3, Rq4</td>
</tr>
<tr>
<td>Dumb</td>
<td>Rq1, Rq3</td>
</tr>
</tbody>
</table>
In order to support integrated specification of common functional quality requirements at the variation points we need to analyse the variants further with respect to ability and quality attribute satisfaction mechanisms.

Looking at the security feature implementation capabilities for the different variants at different data access interface points a domain features function analysis template can generate the common functional quality requirements as shown below:

**Table 3: Functional quality achievement analysis matrix**

<table>
<thead>
<tr>
<th>Phone Variant</th>
<th>Login Interface</th>
<th>Desktop Interface</th>
<th>External Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Pass</td>
<td>Bio</td>
<td>Patt</td>
</tr>
<tr>
<td>SMART</td>
<td>X</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>EVOLVE</td>
<td>X</td>
<td></td>
<td>X</td>
</tr>
<tr>
<td>DUMB</td>
<td>X</td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

Nb. Symbol (X) in the matrix denotes the variant supports the associated security achievement mechanism, Pass(Password), Bio(Biometric) RW(Remote wipe), H/w(Hardware), Enc(Encryption) and Patt(pattern).

Table 3 presents an analysis template that indicates satisfaction of security and privacy quality requirements in the three variants phone data storage function happens in three dimensions (at login, Desktop and External interfaces). However the mechanisms of satisficing the quality requirements generate both common and variable mechanisms possible in the product line as follows:

At Login security variation point, all the three variants share the PIN authentication mechanism of access control, while some support pattern, biometrics or both.

For Desktop security/privacy point all the three variants share auto-screen lock access control but differ in unlocking mechanism of PIN, pattern, biometrics and key-combination.

For External Storage security variation point two variants share remote wipe and encryption capabilities but one has hardware key and the other does not have the functionality.

The analysis above therefore generates three functional-quality requirements at the variation points as shown in Table 4.

**Table 4. Functional quality achievement analysis matrix.**

<table>
<thead>
<tr>
<th>Variation Point</th>
<th>Functional-Quality requirement</th>
<th>Specification ID</th>
</tr>
</thead>
<tbody>
<tr>

<td>Encrypt</td>
<td>VPEExt-Auth(encrypt)</td>
</tr>
<tr>
<td>External Interface</td>
<td>Remote wipe</td>
<td>VPEExt-protect(Rw)</td>
</tr>
</tbody>
</table>
iv) Storage in the repository inform of XML aspectual component

The four common functional-qualities attributes (FQAs) for the three variants at different variation points can thus be developed separately as aspectual components to be attached to the common base architecture at respective join points defined by variation points. In order to make the requirements specification systematic and traceable the functional quality attributes can be stored in XML format in the repository together with the original SRS documents for future reuse.

This approach supports the architects and application engineers while generating new members or variants of the software product line family that is initially restricted by defined scope.

5. DISCUSSION AND CONCLUSIONS

In this paper, we suggested a practical approach for integrating functional quality requirements in SPL requirements documentation in an intuitive way. We have outlined steps in the process of analysis and integration and demonstrated practicality of the proposed approach with a case study.

The proposed approach is based on domain feature model analysis and natural language textual representation, which is the most widely, used methods in SPLE. Literature review shows a lot of variability analysis in functional dimensions while quality variability is considered implicit. Our approach therefore supports early consideration of quality attributes and their subsequent integration into the SPL documentation.

Since natural language and textual description of software requirements can be used to extract functional features and identification of variation points is a continuous activity in all phases including requirement gathering, this work attempted to extract quality attributes variations during analysis that can be represented alongside functional requirements owing to their means of operationalization. This work however is limited to incorporation and representation of quality attributes whose realization is based on functional view of software.

One limitation in this work is the fact that it has not been tested in a complete product line architecture that specifies the rules on how the aspectual components will be connected as well as their relationships, interactions, and dependencies among them. For example very elaborate security quality component implementation can negatively affect usability attribute and cost objectives. We therefore hope to investigate these scenarios in an industrial scope.

State of the art solutions to modern day problems demands automation which has not been accomplished in this work. To encourage adoptability of this approach we intend to develop a tool to manage automated extraction of variation point functional quality attributes using natural language processing techniques and latent semantic analysis abstraction from software product line family requirements documentation.

In future, we aim to explore the impact of weaving quality attributes to functional requirements at variation points considering that quality attributes have conflicts and interdependencies with others.
