ABSTRACT

Facial expression recognition is one of the types of non-verbal communication that is not only commons for human but also plays an essential role in everyday lives. The development of science and technology allows the machine to automatically detect human facial expressions based on images and videos. Numerous facial expression detection methods have been proposed in the literature. This paper presents a method to find three basic facial expressions (neutral, happy, and angry) from two parameter values: smile and eyes-open. The analysis involves a preprocessing step using a combination of pre-designed proprietary algorithm and Luxand library. Firstly, the parameters were mapped into two-dimensional space and then grouped into three clusters using K-means, a popular heuristic clustering method. Secondly, more than 50,000 frames for each video were experimented using the proprietary research data. The result shows that the proposed method successfully performed a simple video analysis of facial expressions.

KEYWORDS

Facial expression, Image processing, Clustering analysis, Image Analysis, Video Processing

1. INTRODUCTION

Automatic human Facial Expression Recognition (FER) has attracted the attention of many researchers, not only from computer science but also from human behavior with a psychology background. However, the fundamental theory of facial expressions generally refers to Ekman [1], a pioneer in the emotion study and their association with facial expressions.

With the advance of science and technology development, FER has opened the possibilities of implementation in human life activities, including social-media-related applications. However, detecting human expression automatically in images or videos is not trivial due to many constraints, although some methods have been proposed and found in the literature [12-16]. Several previous studies [10-11] have shown that the FER method achieved 68.4% and 73.28% accuracy using CNN on the FER2013 dataset.

This paper proposes a method to find facial expression patterns on video based on the smile and eyes-open confidence values obtained from Luxand SDK [2]. Three of six basic facial expressions have been classified, happy, angry, and neutral/normal, using the two parameters: smile and confidence. These parameters are quantitative numbers from 0 to 1 that show if the subject smiles and if the eyes are open or closed. For example, if the result of expression analysis is Smile=0.94768; EyesOpen=0.9998, it indicates that the subject smiles with a confidence level

DOI: 10.5121/ijaia.2021.12503

of 94.7%, and the eyes are open with a confidence level of 99.9%. Figure 1 shows the illustration of the expression analysis of images. The experiment was carried out using the predesigned proprietary facial expression database called DEWI, an Indonesian facial expression dataset collection.

Figure 1. Smile and Eyes-open Values [3]

2. METHODS

Our proposed method is composed of five process blocks, as displayed in Figure 2. To start with, the face detection method was implemented and then followed by the feature selection method using the proprietary algorithm combined with the Luxand framework. This step resulted in two values, smile confidence values, and eyes-open confidence values. Based on these values, the targetted facial expression can be estimated.

Figure 2. Process Blocks of the Expression Recognition Research

2.1. Face Detection Methods

Face detection is a process to localize faces in a digital image. An algorithm called DeWa is developed and applied to detect a facial object in a digital image. The detection step consists of three stages: segmentation, filtering, and localization. The algorithm was successfully tested using a expression database called DWI. The complete explanation of the method can be read in [4]. Specifically, Figure 3 shows the workflow of DeWa.

International Journal of Artificial Intelligence & Applications (IJAIA), Vol.12, No.5, September 2021

Figure 3. Face Detection Framework [4]

2.2. Facial Features

Facial features play an important role in facial expression recognition. In this research, 66 facial features adopted from Luxand were applied. These features show local coordinates of specific areas of a face that are categorized into (i) eyes, (ii) eyebrows, (iii) nose, (iv) mouth, (v) nasolabial, (vi) chin, (vii) contours. Figure 4 shows the local features of a face and an example of facial features marker number.

Figure 4. Example of Facial Features and Their Coordinate [2]

All features were processed based on the comparison between neutral or normal faces with other facial expressions. The distance between the two images was calculated and features were displayed the features in three classes: up, down, and regular (no changes). Figure 5 illustrates the process.

2.3. Smile Detection and Eyes-open Detection

A smile can be considered as a form of micro-expression: brief facial cues that reveal the natural intention of a person. When a person smiles, his facial muscles will contract. A natural smile will include wrinkles, pushed-up cheeks, and a movement from the muscle that orbits the eye.

A Swedish anatomist, Carl-Herman Hjortsjo [5], has classified human facial movements on the face. Then, Ekman and Friesen [6] have improved this method and created the Facial Action Coding System (FACS). In 2002, Ekman, Friesen, and Joseph C. Hager published a significant update to FACS [7]. FACS is a general system to systematically categorize human facial expressions and is used in various disciplines, including by psychologists, neuro-analysts, and animators. Combinations of action units can build a facial expression in FACS [8]. Figure 6 shows the sample FACS coding of a facial expression.

Figure 6. Sample FACS Coding of a Fear Expression

2.4. Modified K-means Clustering

K-means is an unsupervised method for clustering and is mainly used by researchers for various data mining implementations. However, traditional K-means have limitations. One of them is that to process the data, the number of a cluster has to be stated. This condition does not meet the requirement if the number of clusters to be processed is unknown. For this purpose, the K-means algorithm is was modified to solve this condition so K-means can run without a predefined number of clusters [9].

International Journal of Artificial Intelligence & Applications (IJAIA), Vol.12, No.5, September 2021 Mathematically, K-means minimizes a function as follows:

$$K = f(x) = \sum_{i=1}^{m} \sum_{x_j \in C_i} D(x_j, \mu_i)^2 \quad (1)$$

 $D(x_j, \mu_i)$ is the distance between its closest centroid. There are numerous distance functions that can be used in measuring the distance between objects. However, the Euclidean distance is the most straightforward distance measurement used for calculation. The Euclidean formula for calculating the distance between two objects is presented below:

$$D_{i,j} = \sqrt{\sum_{k=1}^{n} (x_{ik} - x_{jk})^2}$$
(2)

As previously stated, in K-means, the number of clusters to classify has to be defined. In modified K-means, this limitation was eliminated by optimizing the value of k. The values were defined sequentially and processed to evaluate the highest-minimal value. The optimization function is defined as:

$$V = \frac{J'}{N \square \delta_{\min}^2} + \sum_{i=1}^{k'} \frac{1}{1 + |C_i|}$$
(3)

 $\delta_{\min} = \min_{\neq j} \{\delta(\mu_i, \mu_j)\}$ is the centroids' shortest distance, k points to a number of the selected cluster provided with enough data, J' is used partly for clusters chosen, and $|C_i|$ is the cluster's cardinality. Thus, the first term of the above equation represents the goal function: finding clusters that were well-separated for better solutions. The second term was used for penalty factors for clusters with small members.

2.5. Generating Basic Facial Expression

The facial expression parameters were generated based on the ground-truth data (see Figure 7) that were processed using K-means clustering with k=3. The result of clustering is presented in Table 1 below.

Expressions	Smile	Eyes-open
Neutral	0.07048509	0.9998214
Нарру	0.93574368	0.9618265
Angry	0.14346801	0.9572292
Neutral	0.07048509	0.9998214

Table 1. Result of the Clustering Process

The values show the centroids of each facial expression based on the parameters of smile and eyes-open. The centroid will be used for the distance calculation of tested data to approximate facial expression results.

3. RESULTS AND ANALYSIS

3.1. Data for Experiment

The experimental data provided by the Psychology Department of Universitas Padjadjaran are in the form of images and videos. The data were gathered through another research on the social anxiety of West Java people. Image data are considered as training data to generate the ground truth of facial expression clusters (refer to Table 1). The data characteristic of these images is shown in Table 2.

Expressions	Image Type and Resolution					
Expressions	# Grayscale	Resolution	# RGB	Resolution		
Neutral	247	720 x 960	32	2085 x 3139		
Нарру	625	720 x 960	29	2164 x 3257		
Angry	671	720 x 960	18	1865 x 2808		

Table 2. Image Characteristics of Experimental Data

These image data were processed to obtain smile and eyes-open confidence values. The values were then mapped into a 2D-smile-eyes-open chart which shows the characteristics distribution of facial expression data as presented in Figure 7.

Figure 7. Ground-truth Data Mapping Space

The neutral, happy, and angry distribution of facial expressions are represented by point-shape colors grey, green, and red. As seen in the figure, the red dots and the green dots are more dominant, while the grey dots are almost invisible. This condition can happen due to fewer neutral data images (257 compared with 625 and 671, refer to Table 2).

The method was then tested using the video data. The characteristic of the videos is presented in Table 3.

Video	Size (MB)	Time	Resolution	Rates	# Frames
А	512	36:55:00	800 x 600	25 fps	55,380
В	739	53:19:00	800 x 600	25 fps	79,976
С	625	49:30:00	800 x 600	25 fps	74,255
D	403	31:42:00	800 x 600	25 fps	47,561

Table 3. Video Characteristics of Experimental Data

3.2. Discussion

To validate the approach, the ground-truth data were evaluated using clustering parameters. The result is presented in Table 4 below.

Expressions	#GT	#Neutral	#Happy	#Angry	Performance (%)
Neutral	279	237	35	7	84.95%
Нарру	654	4	<u>618</u>	32	94.50%
Angry	689	505	72	<u>112</u>	16.26%

Table 4. Evaluation of Facial Expression Images

The evaluation result shows the excellent performance of the clustering method for neutral and happy expressions. The angry facial expression can be considered as a false result because it gave a minimal performance. Further analyzing this error, it was found that most of the images in the angry group have higher eyes-open confidence values, but lower smile confidence values. Thus, images with angry expressions were considered similar to images in a neutral expression. Other parameters were considered needed to differentiate between those two expressions.

The testing video was processed frame-by-frame sequentially. Initially, each frame was analyzed to obtain smile and eyes-open confidence values. These values were then calculated with the result of clustering (refer to Table 4) using the Euclidean distance formula (see Equation 1). Finally, the decision of facial expression was taken based on the smallest distance value. The result of video processing is presented in Table 5.

Video	# Frames	#Neutral	#Happy	#Angry
А	55,380	14,791	8,338	32,244
В	79,976	6,351	26,645	46,979
С	74,255	42,071	5,856	26,327
D	47,561	5,874	19,367	22,319

Table 5. Analysis of Facial Expression Videos

The numbers of happy facial expressions that are greater than the numbers of neutral facial expressions are found in Video B and Video D. On the other hand, Video A and Video C show that a neutral expression is more often found than a happy expression, which is presented graphically in Figure 8. The angry expression numbers shown in Table 5 were not analyzed and could be considered false detection errors. It is displayed for documentation only.

Figure 8. The result of Video Analytic in Graphics

3.3. Ekspreso: Testbed Software for Evaluation

For the purpose of this research, a testbed software for video and image expression evaluation called Ekspreso was developed. The software is built on .NET and runs on Microsoft Windows operating system. It can be used to evaluate the performance of our algorithm using images and videos. Figure 9 shows the expression evaluation for images, and Figure 10 depicts the expression evaluation for videos. The face areas are covered due to human-right privacy.

4. CONCLUSIONS

In this paper, a method to find patterns of facial expressions is presented based on two parameters: smile and eyes-open confidence level values. A non-supervised method, K-means, was succesfully applied for clustering the data based on the proprietary ground truth images. The values were calculated to obtain information about three facial expressions: neutral, happy, and angry. It is shown that this method has successfully presented the accurate result for the two expressions: neutral and happy. The work is still in progress to improve the accuracy of neutral expression detection to reach the maximum accuracy as happy expression detection. However, for angry expressions, the performance was not remarkable. In this case, further research is recommended to explore and implement other techniques to solve this problem and increase the detection accuracy for angry expression.
